NO. 63

IN THIS ISSUE

1. Seed Catalogs
2. Tomato and Potato Late Blight Forecasting
3. Asphallic Mulches
4. Blotchy Ripening of Tomatoes
5. New Variety Releases
6. Celery Pinkrot and Lettuce Drop
7. Brief Notes from Here and There
   a. Watermelon Diseases
   b. Spacing in Sweet Corn
   c. Students Needed in Agriculture

1. Seed Catalogs

At one of the Agents' Training Schools last fall, a few agents requested that we supply you with a list of names and addresses of seed companies from which they could obtain descriptive and price catalogs. These catalogs are handy references and should be made a regular part of the library of all agents working in vegetable production.

The partial list of companies included below can supply you with information on description of varieties, source of seed of regular crops and hard-to-find specialty crops, supplies, chemicals, etc. We have listed eighteen companies and where possible, have indicated the crops or items in which they specialize. Write these companies for their descriptive catalogs preferably or their price catalogs if the former is not available.

COMMERCIAL VEGETABLES *

Abbott and Cobb
4744-46 Frankford Avenue
Frankford, Philadelphia 24, Pa.

Asgrow Seed Company
New Haven 2, Connecticut
2. Tomato and Potato Late Blight Forecasting

The U. S. Department of Agriculture and a number of state Experiment stations have investigated the possibility of developing a forecasting service for potato and tomato late blight. Conditions conducive to late blight development have been worked out and were tried on an area basis in one location in Florida last year.

Even though area-wide forecasting services are not available in the potato and tomato growing areas of Florida, growers should be made aware of the environmental conditions leading to late blight development. This type of information could be used by the grower to adjust his spray schedule with a better degree of judgement than otherwise.

Conditions favorable to late blight developments are:

1. A total

*This list is not intended to be exclusive and no discrimination or endorsement is implied.
rainfall of 1.00 inches or greater over ten consecutive days plus,
(2) seven consecutive days of temperature when the maximum ranges
between 50° and 77°F. High relative humidity and heavy dews con­
tribute to the moisture requirement. A temperature maximum of 85°F. on
any day breaks the "seven consecutive day" requirements which means
late blight is not apt to develop immediately. A break, therefore, in
either temperature or moisture requirements breaks the cycle and cal­
culations should be started again.

3. **Asphaltic Mulches**

Several stations in Florida have tested asphalt-like petroleum
mulches on a number of vegetables for the past two years. Preliminary
results appear quite promising. Some of the benefits that have been
observed by the use of asphaltic mulch are: (1) longer retention for
more effective action of soil fumigants, (2) raising soil temperatures
when cold soils are a limiting factor, (3) reduction of wind and rain,
erosion and, (4) possibly increasing effectiveness of herbicides.

Asphaltic mulch requires special equipment for application. Field
tests are being conducted in several counties in the state. The mat­
erial has label clearance for use commercially on beans and cucurbits.
Asphaltic mulch is still in the developmental stage but should be
watched as it offers some good possibilities in Florida.

4. **Blotchy Ripening of Tomatoes**

Are blotchy ripening, graywall and white tissue in tomatoes the
same? Yes, says Dr. Phil Minges, Extension Vegetable Specialist from
Cornell University. He has just completed a survey of Mexican and
Florida tomato growing areas and is also familiar with California and
New York state deals. He reports that the problem is found in all of
these areas.

He has some evidence which indicates that all of the conditions
mentioned above are just different manifestations of the same dis­
order which is probably physiological in nature. He has been able to
reproduce this complex of disorders under greenhouse conditions in
nutrient culture studies.

If Dr. Minges’ contention is correct, a long step forward in
the ultimate solution of the problem has been taken. His ideas on
blotchy ripening have yet to be proven. Nevertheless, they will stim­
ulate some thinking and possibly some additional research.

5. **New Variety Releases**

The Florida Agricultural Experiment Station is releasing two
southern pea varieties in the near future. Look for the release
circular due out within a month or so. Floricream is a crowder type, cream southern pea with resistance to wilt. It is a good yielder and can be used for fresh market, freezing and canning.

Snap pea is a new type of southern pea. It was developed primarily for use in the snap stage. This variety should be in demand by processors who process snapped and shelled peas together.

Seed of these varieties will be increased and if everything goes well, they should be available for commercial plantings in the fall of 1964.

6. Celery Pinkrot and Lettuce Drop

Circular 193C lists a recommendation for control of lettuce drops with weekly sprayings of 2 pounds of ferbam plus 2 pounds of hydrated lime. Recent work indicates that this is also the best control available for celery pinkrot. Both of these diseases are caused by the fungus, Sclerotinia sclerotiorum. Sclerotinioid disease is another name for the disease which may attack crucifers and other vegetable crops as well.

7. Brief Notes from Here and There

a. Watermelon Diseases

Watermelon mosaic and bacterial spot have shown again in south Florida. Be on the lookout for these diseases. Suggestion for checking bacterial spot is the use of basic copper. No control is available for watermelon mosaic.

b. Spacing in Sweet Corn

Considerable research in progress now and in the past on organic soils shows that spacing sweet corn too closely results in reduction in ear size and ultimately higher grade out. Rows 23 to 32 inches apart and spacing of 8 inches between plants is recommended for the best growing conditions.

c. Students Needed in Agriculture

Although our enrollment in the College of Agriculture is on the increase, more students are needed. Students showing a preference for Agriculture when making application for entrance to the University of Florida stand an excellent chance of being admitted. The College of Agriculture has a quota for more students than it presently has registered.

Sincerely,

James Montelaro
Associate Vegetable Crops Specialist

P. S. Jamison, Head
Mason E. Marvel
Associate Vegetable Crops Department Specialist
